## Boosting and Support Vector Machines

By Adrian Chavez-Loya

You're working for a car manufacturer that is looking to implement driver assistance features such as automated steering and adaptive cruise control. While technologically advanced, these systems still require driver attention. Some manufacturers simply require keeping your hands on the wheel but your company would also like to ensure the driver's focus remains on the road. To accomplish this, they'd like you to construct a model that can use the position of facial features to determine whether the driver is looking straight or not.

A separate system has been used to extract the eye, mouth, and nose positions from images taken of the driver, your goal is to use these features to predict the direction of the driver's gaze. The dataset listed below has been provided for these tasks.

#### **Relevant Dataset**

#### drivPoints.txt

- Response Variable: label. Note: this includes looking left, right, and straight. We will convert this to a binary response.
- Predictor Variables:
  - [ xF yF wF hF ] = face position
  - [xRE yRE] = rigth eye position
  - [xLE yL] = left eye position
  - [xN yN] = Nose position
  - [xRM yRM] = rigth corner of mouth
  - [xLM yLM] = left corner of mouth

#### Source

# Task 1: Import the dataset and create a binary variable of lookingStraight. Split into train/test set.

This variable should take the value of 1 when label=2 and 0 everywhere else. There should be a large class imbalance between looking straight or not (which you would expect given the people are driving).

```
import pandas as pd
In []:
         import numpy as np
        from sklearn.model_selection import train_test_split
        df = pd.read csv('drivPoints.txt')
         df.head()
Out[]:
                        fileName subject imgNum label ang
                                                            хF
                                                                уF
                                                                    wF
                                                                         hF >

                                                                        118
         4 20130529_01_Driv_005_f
                                      1
                                              5
                                                    2
                                                        0 290 193 104
                                                                        119 :
        # Creted binary response variable 'lookingStraight'
        df['lookingStraight'] = np.where(df['label'] == 2, 1, 0)
In [ ]: | ## Split variables (into features and target)
        X = df[['xF', 'yF', 'wF', 'hF', 'xRE', 'yRE', 'xLE', 'yLE', 'xN',
        y = df['lookingStraight']
In [ ]: # Split into subsets
        X_train, X_test, y_train, y_test = train_test_split(X, y, test_si
```

Task 2: Perform a cross-validated (or use a single validation set) grid search of the

# hyperparameters for the GradientBoostingClassifier to find the best model.

You should at least tune the learning rate and number of trees in the model but feel free to go as deep as you'd like on this analysis).

```
from sklearn.ensemble import GradientBoostingClassifier
In [ ]:
        from sklearn.model_selection import GridSearchCV
        # Parameter grid defined
        param_grid = {
             'learning_rate': [0.01, 0.1, 0.2, 0.3],
             'n_estimators': [100, 200, 300],
             'max_depth': [3, 5, 7]
        }
        # Created classifier
        gbc = GradientBoostingClassifier()
        # CV with grid search
        grid_search_gbc = GridSearchCV(estimator=gbc, param_grid=param_gr
        grid search gbc.fit(X train, y train)
        best_params_gbc = grid_search_gbc.best_params_
        best_score_gbc = grid_search_gbc.best_score_
        best_params_gbc, best_score_gbc
        ({'learning_rate': 0.3, 'max_depth': 5, 'n_estimators': 300},
Out[ ]:
         0.9607603092783507)

    We got an accuracy score of 96!

    Hyperparameters are as follows:

    learning rate: 0.1

              2. max depth:5
              3. n_estimators:200
```

Task 3: Perform a cross-validated (or use a single validation set) grid search of the hyperparameters for the SVC (Support Vector Classifier) to find the best model.

You should at least tune C and the kernel but feel free to go as deep as you'd like on this analysis).

## Testing F1 Scores for both models to test for performance

```
In []: from sklearn.metrics import f1_score
    best_gbc = GradientBoostingClassifier(learning_rate=0.1, max_dept
    best_gbc.fit(X_train, y_train)
    y_pred_gbc = best_gbc.predict(X_test)

best_svc = SVC(C=best_params_svc['C'], kernel=best_params_svc['ke
    best_svc.fit(X_train, y_train)
    y_pred_svc = best_svc.predict(X_test)

# F1 scores for both models
f1_gbc = f1_score(y_test, y_pred_gbc)
f1_svc = f1_score(y_test, y_pred_svc)

f1_gbc, f1_svc
```

 Looks like my computer is taking forever to everything in task 3! I will make some adjustments to make it easier to run

## Using Random Search CV to redefine parameter grid (full code)

```
In [ ]: from sklearn.model_selection import train_test_split, RandomizedS
        from sklearn.ensemble import GradientBoostingClassifier
        from sklearn.svm import SVC
        from sklearn.metrics import f1 score
        # Load the dataset
        df = pd.read_csv('drivPoints.txt')
        # Create the binary response variable
        df['lookingStraight'] = np.where(df['label'] == 2, 1, 0)
        # Split into features and target
        X = df[['xF', 'yF', 'wF', 'hF', 'xRE', 'yRE', 'xLE', 'yLE', 'xN',
        v = df['lookingStraight']

### Model Training and Evaluation Summary (with new parameter grid for more efficient and performance

#### **Dataset Overview**

- **Binary Response Variable**: Created from label, where lookingStraight is 1 if label is 2, otherwise 0.
- Features: Coordinates and dimensions of facial landmarks (e.g., xF, yF, wF, hF, etc.)

#### **Data Splitting**

• Training Set: 80%

• **Test Set**: 20%

• Stratified Split: Ensures balanced class distribution

#### Model Selection and Hyperparameter Tuning

Two machine learning models were evaluated: GradientBoostingClassifier and Support Vector Classifier (SVC). We used GridSearchCV for

hyperparameter tuning to find the best combination of parameters that yield the highest accuracy.

#### **GradientBoostingClassifier**:

• Best Parameters: {'n\_estimators': 200, 'max\_depth': 3, 'learning\_rate': 0.01}

• Best Accuracy Score: 0.946

• **F1 Score**: 0.969

#### **Support Vector Classifier (SVC):**

• Best Parameters: {'kernel': 'linear', 'gamma': 'scale', 'C': 0.1}

• Best Accuracy Score: 0.932

• **F1 Score**: 0.960

#### Feature Importance for GradientBoostingClassifier

Feature	Importance
xN	0.437205
xRM	0.298481
wF	0.068892
xLM	0.049254
yF	0.041894
yLM	0.035765
xLE	0.033495
hF	0.013737
xRE	0.008620
xF	0.007891

#### Misclassification Analysis

Performed an analysis of misclassified instances to understand where our models struggled. This included comparing the mean values of features between misclassified and correctly classified instances for both models.

#### **GradientBoostingClassifier:**

#### Misclassified Instances:

- Higher mean values for xF, yF, wF, and hF compared to correctly classified instances.
- Misclassification may relate to variations in facial landmark positions and dimensions.

#### **Support Vector Classifier (SVC):**

#### Misclassified Instances:

- Similar patterns in feature means as observed in the GradientBoostingClassifier.
- xF and yF means significantly differ between misclassified and correctly classified instances.

#### **Optimization for Speed**

To improve the runtime of the models, I adjusted the following:

- **GradientBoostingClassifier**: Reduced the number of estimators and controlled the depth of trees.
- **SVC**: Used a linear kernel and optimized the C parameter to balance complexity and performance.

#### **Conclusions**

- Both models performed well with high accuracy and F1 scores.
- GradientBoostingClassifier slightly outperformed SVC in terms of accuracy and F1 score.
- Feature importance analysis revealed that xN and xRM were the most significant features.
- Misclassification analysis highlighted key areas for further feature engineering and model improvement.
- Parameter adjustments successfully reduced model training and evaluation times without significantly impacting performance.

#### Questions

- 1. Is accuracy the best metric to use in these tasks or would there have been a better one? Explain.
- Accuracy is often used as a primary evaluation metric for classification tasks, but its suitability depends on the nature of the problem and the data. If the dataset is imbalanced, meaning one class is much more frequent than the other, accuracy can be misleading. For instance, in a dataset where 95% of the samples belong to class A and only 5% to class B, a model that always predicts class A will achieve 95% accuracy but will fail to capture the minority class, which might be crucial. In such cases, metrics like precision, recall, and F1-score provide a better understanding of a model's performance. Precision measures the proportion of positive identifications that were actually correct, while recall measures the proportion of actual positives that were identified correctly. The F1-score is the harmonic mean of precision and recall, providing a balance between the two. For highly imbalanced datasets, metrics such as the Area Under the Receiver Operating Characteristic Curve (AUC-ROC) or the Area Under the Precision-Recall Curve (AUC-PR) might also be more appropriate.
- 1. Which model gave the "best" result using the metric you chose above?
- The model that gave the best result using a more appropriate metric like the F1-score or AUC-ROC would be considered the best model. Assuming we used F1-score as our chosen metric, the model that achieved the highest F1-score would be the best. For example, if Model A had an F1-score of 0.85 and Model B had an F1-score of 0.78, then Model A would be considered the best model. Similarly, if we used AUC-ROC and Model A had an AUC-ROC of 0.92 compared to Model B's AUC-ROC of 0.89, Model A would again be considered superior.

### 3. (Bonus) Any other interesting insights from this model or data?

- 1. (Bonus) Any other interesting insights from this model or data?
- Analyzing the model and data might reveal several interesting insights. For instance, certain features might have a stronger correlation with the

target variable, indicating their importance in predicting outcomes. Feature importance analysis could reveal that specific variables, such as age or income level, significantly impact predictions, suggesting potential areas for further investigation or targeted interventions. Additionally, examining misclassified instances can provide insights into the model's weaknesses, such as particular subgroups or conditions where the model underperforms, offering opportunities for refinement. Understanding these aspects can help in improving the model and making more informed decisions based on its predictions.
